

ABSTRACT:

A saddle-shaped deflection coil (21) for a cathode ray tube has a beginning (22) of a current-supply wire which is largely detached from a flange (17) of the deflection coil, which flange does not exhibit an impression of the beginning of the current-supply wire. The deflection coil is wound in a manner such that, after winding and baking of the coil, the beginning does not have to be pulled loose from the flange, as has been customary hitherto.

(Fig. 4B).
